#### I. INTRODUCTION

During the second HPR1000 Working Group (HPR1000WG) meeting [Ref. 1], the participants expressed an interest in understanding the similarities and differences in regulatory approaches to hazards assessment of the member countries, and the potential implications of these regulatory approaches on the design of the HPR1000 technologies. A hazards technical expert's subgroup (TESG) was subsequently established to engage on hazards-related topics, and to identify common positions, where applicable.

This technical report is based on engagements between representatives of the Hazards TESG, and the responses provided to a questionnaire that was developed to capture the regulatory approaches used in relation to identifying, characterising, screening, and assessing hazards in each member country. The questionnaire developed by the Hazards TESG, with each country's responses, is provided in the appendix to this document.

The purpose of this report is to identify the similarities and differences in regulatory approaches, and where applicable, to identify common positions for safety in relation to hazards and/or the conclusions of the safety analysis for the HPR1000 design. This report provides a high-level summary of each country's regulatory philosophy (Section II) and then due to the broad nature of hazards provides several pertinent, example hazards that illustrate how these regulatory approaches are applied in practice. These examples are used to highlight similarities and differences in regulatory approaches, and to identify any implications such as the expectation for additional analyses. The report concludes by explicitly highlighting common practice and summarising any potential implications of differences in regulatory practice.

The scope of this report is limited due to the varying status of each participating nation's regulatory assessment of the HPR1000 reactor technologies. This report does not provide commentary on the implications of any differences in regulatory approaches/expectations for hazards on the design of the HPR1000 plant and its structures, systems, and components.

Validity: until next update or archiving

#### II. OVERVIEW OF APPROACHES TO HAZARDS

#### **SUMMARY**

The first meeting of the Hazards TESG took place at the third HPR1000 WG meeting [Ref. 2]. At this meeting the hazard-related topics of interest were discussed and agreed by the members of the Hazards TESG. The regulatory approaches to certain topics were identified as being significantly different between members, such that it was considered unlikely that a common position could be achieved. For example, the design basis event expectations for external hazards vary significantly between members of the Hazards TESG, and in some instances the expectations for derivation of a design basis event also varies between different external hazards (e.g. return periods). These topics were therefore excluded from further consideration. It was noted that there were more comparable expectations for internal hazard design basis events. Further, following the events at Fukushima-Daiichi all regulators have moved to a position where designs are expected to include resilience against rare and severe hazards, which are additional to design basis events, and represent less frequent events and more challenging accident conditions.

As a result of these discussions, the following topics were identified for further consideration through the development of a questionnaire. The associated questions agreed by the TESG are listed in Annex 1 along with each member response. The topics included in the questionnaire are outlined below:

- High Energy Pipe Failure
- Dropped Loads
- Internal missiles
- Combined hazards in areas of high risk
- Multi-hazard barriers
- Expectations on layout (including exceptions to segregation)
- Fire modeling (including validation and verification of the analysis)
- Beyond design basis events
- Maximum credible events

Validity: until next update or archiving

Version: 0.1 (Draft)

The approach of each Regulator to these hazard topics and the questionnaire responses were discussed during the fourth HPR1000 WG meeting [Ref. 3]. The vendor<sup>1</sup> for the HPR1000 reactor technology provided a presentation that described the hazards considered in the HPR1000 design, and the associated design bases [Ref. 4], based on the relevant Chinese codes and standards. The vendor and NNSA consider the standards that have been applied to be consistent with the guidance provided in IAEA safety standards.

All national regulators participating in the HPR1000 WG ensure their national guidance documents are aligned with IAEA documentation relevant to hazards. Therefore, at a principles level, the regulatory expectations for the selected hazards are similar between the members of the Hazards TESG. For example, all regulators expect a range of analysis approaches to be used to evaluate hazards and their effects on a design including: deterministic approaches, design basis analysis, analysis of design extension conditions without significant fuel degradation (including demonstrating an absence of cliff edge effects), probabilistic safety analysis and severe accident analysis. The technical discussions also demonstrated that there are differences in the application of these highlevel expectations for most hazards, and in particular where detailed methodologies were discussed for internal hazards. These differences are relevant to the assumptions used in the identification, screening, and characterisation of each hazards (including combinations), and also the analysis methods employed.

The appendix provides a detailed summary of the Regulatory expectations and relevant good practice that is adopted for specific hazards in response to the questionnaire developed by the Hazards TESG. This table provides a clear overview of commonality and differences between each member nation and forms the basis for this report.

Using the detailed information from the appendix, the remainder of this section presents the general approach of each Regulator to hazards. In the following sections (III - V) several pertinent hazards are reviewed as examples of how the various regulatory approaches are applied in practice. These examples highlight similarities and differences

1 The Vendor is a representative of the two design authorities for HPR1000 reactor technology; China General Nuclear, the designer of option 1, and China National Nuclear Corporation, the designer of option 2.

Validity: until next update or archiving

Version: 0.1 (Draft)

in regulatory approaches to identify any implications for the HPR1000 design, such as the expectation for additional analyses.

#### **CHINA**

The Chinese nuclear Regulator (NNSA) operates a prescriptive regulatory approach. High-level requirements are provided in the HAF documents (safety requirements), with the detailed technical requirements provided in the supporting HAD documents (safety guides). Consideration of hazards (and combinations) is a requirement. The standards relevant to hazards are:

- HAF101-1991 Safety Regulation for Nuclear Power Plant Siting
  - HAD101/01-1994 Earthquake Problems in Relation to Nuclear Power Plant Sitting
  - HAD101/03-1987 Site Selection and Evaluation for Nuclear Power Plants with Respect to Population Distribution
  - HAD101/04-1989 External Human Induced Events in Relation to Nuclear Power Plant Siting
  - HAD101/06-1991 Relationship between Nuclear Power Plant Siting and Hydrological Geology
  - HAD101/09-1990 Determination of design basis Flood for Nuclear Power Plant Sited by Coast
  - HAD101/10-1991 Extreme Meteorological Events in Nuclear Power Plant Siting (Excluding Tropical Cyclone)
  - HAD101/11-1991 design basis Tropical Cyclone for Nuclear Power Plants
  - o HAD101/12-1990 Foundation Safety Problems of Nuclear Power Plants
- HAF102-2016 Safety regulation for design of nuclear power plants
  - HAD102/04-2019 Protection Design against Internal Hazards (other than Fire and Explosion) in Nuclear Power Plants
  - o HAD102/05-1989 External Man-Induced Events in Relation to NPP Design

Validity: until next update or archiving

Version: 0.1 (Draft)

 HAD102/11-2019 Protection Design against Fire and Explosion in Nuclear Power Plants

Chinese standards are benchmarked with IAEA documentation to ensure consistency of approach.

#### **UNITED KINGDOM**

In the UK, the Office for Nuclear Regulation (ONR) regulates nuclear safety, security, safeguards, transport, and conventional health and safety on licensed sites according to the UK goal setting regulatory framework. In line with that framework ONR applies a goal setting regulatory philosophy that is consistent with the UK's health and safety law. Fundamental to this approach is the legal duty for duty holders to reduce risks so far as is reasonably practicable (SFAIRP). As part of this, ONR looks for operators of licensed nuclear installations to demonstrate that the normal requirements of good practice in engineering, operation and safety management are met and that risks in operation are reduced to be As Low As Reasonably Practicable (ALARP). This places duties on both the design organisations and on future licensees and operators.

ONR publishes its high-level expectations for nuclear safety in the Safety Assessment Principles (SAPs). Expectations for hazards are explicitly covered by a total of 19 SAPs; EHA.1 – EHA.19, but there are many other related and relevant SAPs. The ONR SAPs are considered fully in line with IAEA guidance and standards. The SAPs cannot reflect the breadth and depth of the entire suite of IAEA publications and so ONR explicitly identify those documents as relevant good practice within technical assessment guides (TAGs). The TAGs provide more specific, technical guidance on a range of safety topics. These provide guidance to ONR's inspectors in making judgements on the adequacy of a dutyholder's safety documentation against the ALARP principle. Relevant technical assessment guides for hazards include:

- NS-TAST-GD-013 for External Hazards
- NS-TAST-GD-014 for Internal Hazards

In addition to the SAPs and technical assessment guides, ONR has also published additional technical guidance for new reactor designs wishing to be assessed through the UK's Generic Design Assessment (GDA) process.

Validity: until next update or archiving

Version: 0.1 (Draft)

 ONR-GDA-GD-007 - New Nuclear Power Plants: Generic Design Assessment Technical Guidance

The GDA process enables ONR and other regulators to assess the safety, security, and environmental implications of new reactor designs, separately from applications to build them at specific sites. GDA is a stepwise process, with the assessment getting increasingly detailed at each step following the claims, arguments, and evidence (CAE) to safety documentation. At the time of writing the generic UK HPR1000 design is being assessed by ONR through its GDA process, to determine if a Design Acceptance Certificate (DAC) can be issued. A nuclear site licence would still need to be obtained by any operator of HPR1000 technology before the reactor design could be deployed on a specific site in Great Britain.

Demonstrating that risks related to hazards are reduced to be ALARP does not require in all cases an analytical quantification of risk and benefits, but operators of licensed installations use relevant good practice (RGP) to demonstrate the adequacy of their approach against the ONR SAPs, including those relevant to hazards. RGP is the minimum requirement by which the operator can demonstrate the legal requirement of reducing safety risks to be ALARP. The ONR SAPs recognise IAEA publications as RGP via the TAGs. The use of both a goal setting approach and RGP provides operators of licensed sites the flexibility to adopt the most relevant guidance for any specific scenario, so long as this is adequately justified in their safety documentation.

#### **SOUTH AFRICA**

The South African nuclear Regulator's (NNR) approach to the regulation of nuclear safety and security takes into consideration:

- the potential hazards associated with the facility or activity;
- the need for the authorisation holder to establish safety related programmes commensurate with nuclear and radiation risks; and
- the requirement to exercise regulatory control over technical aspects such as the design and operation of a nuclear facility.

The approach highlights the fundamental principle that the authorisation holder retains the primary responsibility for safety of its facilities and activities. The regulatory philosophy adopted by the NNR is a hybrid employing methodologies and principles based on the

Validity: until next update or archiving

Version: 0.1 (Draft)

approach taken in the regulatory framework, the maturity of the authorisation holder, and international developments related to regulation and emerging safety standards and issues.

The NNR has adopted a process-based approach in regulating facilities and activities. This entails identifying key processes to manage nuclear and radiation safety for facilities and activities. This approach is supported by the NNR requiring the use of a risk analysis which is used for regulatory decision making related to events that impact adversely on nuclear and radiation safety.

The authorisation holder is required to demonstrate that safety related aspects such as ALARA are applied to the satisfaction of the NNR. The NNR requires authorisation holders to demonstrate application of good engineering practice and justify the use of codes and standards.

The NNR's Regulatory Framework consists of legally binding requirements by International Safety Conventions, laws passed by Parliament that govern the regulation of South Africa's nuclear industry, regulations, authorisations, conditions of authorisations, requirements, and guidance documents that the NNR uses to regulate the industry. Requirements are developed in conjunction with the applicable authorised action and effectively cover all the relevant requirements on the holder.

The NNR enforces these requirements on all applicants and authorisation holders. Certain requirements in the legislation are prescriptive to the extent that no further elaboration is necessary. Other requirements are broad in nature.

The NNR establishes additional requirements based on international best practices. These requirements are registered either directly in the authorisations or in "Requirements Documents".

The NNR Safety Standards are premised on international standards such as the IAEA Safety Standards, the UK NII Safety Principles and the WENRA Reference levels. The safety standards provide the principal safety criteria relating to risk criteria, and dose limits for normal operating conditions, applicable to members of the public and workers.

The safety standards further lay down principal radiation and nuclear safety requirements which are applied to all nuclear installations and other regulated actions, and include the following:

Validity: until next update or archiving

Version: 0.1 (Draft)

- Defense-in-depth
- ALARA
- Good engineering practice
- Quality management
- Accident management and Emergency Preparedness
- Safety Culture
- Graded approach

The radiological dose and risk limits for the public and workers relate directly to the objectives of nuclear and radiation safety and are therefore considered the most fundamental yardsticks against which to assess nuclear safety, contributing towards a more consistent and transparent basis for regulatory decision making. The dose limits are consistent with the IAEA Basic Safety Standards.

For the existing Koeberg nuclear power station, the applicable laws, regulations, codes, and standards that were used in its design, construction and manufacture were basically those used in French reference stations. Whenever French safety rules did not cover the scope of South African or US rules, the US rules, according to how they were interpreted for the reference station, and the South African rules were applied. Where other international regulations apply for Koeberg, they are referenced in the Koeberg SAR.

Amongst the many general nuclear and radiation safety principles that underpin and form the basis of the NNR Safety Standards, the following one is of relevance to the topic of this report:

The authorisation holder must demonstrate effective understanding of the hazards and their control for an action or facility through a comprehensive and systematic process of safety assessment. The safety assessment must incorporate both deterministic and probabilistic approaches where appropriate.

#### **ARGENTINA**

The Argentinian nuclear Regulator (ARN) operates a goal setting regulatory approach. High-level regulatory requirements and expectations are established in the "AR" regulations which are harmonised with the IAEA safety standards. AR regulations have a "performance" based character by which the way of achievement of safety objectives, is based on the appropriate licensee's decision making. Licensee has flexibility in

Validity: until next update or archiving

Version: 0.1 (Draft)

adopting additional guidance for development of submissions as long as they demonstrate to be adequate and its implementation justified.

The relevant AR regulations include the following:

- AR 10.10.1 Site Evaluation for Nuclear Power Plants,
- AR 3.1.3 Radiological Criteria for Accident Conditions in Nuclear Power Plants,
- AR 3.2.1 General Safety Criteria for Design of Nuclear Power Plants,
- AR 3.10.1 Protection against Earthquakes in Nuclear Power Plants.

#### III. PIPE BREAKS

This section compares the regulatory approaches of the HPR1000 Hazards TESG with respect to pipe breaks, to identify areas of common practice and key differences. The implications of these differences in regulatory approach are considered with respect to the design of the HPR1000.

The pipe breaks hazard includes high, medium and low energy pipe systems. Of these, high energy pipe failures are the most energetic and usually associated with bounding load cases and consequential hazards. Consequently, the remainder of this section describes each member nation's regulatory expectations relating to high energy pipe failures. It should be noted that other (medium and low) energised pipe systems may need to be analysed under different regulatory regimes, to evaluate the consequences of consequential hazards, such as internal flooding.

#### SCOPE: EXCLUSIONS AND SCREENING CRITERIA

All regulators in the Hazards TESG consider IAEA guidance [Ref. 5] provides a suitable definition of a high energy system. This guidance defines a system as being high energy if it operates at a pressure equal or greater than 2.0 MPa and/or the operating temperature is 100°C or greater in the case of water or equivalent in line (other limits may apply for other fluids). Some nations may choose more conservative parameters that will lead to additional systems being screened-in for assessment (e.g. US NRC NUREG 0800 defines high energy pipelines as having a pressure equal or greater than 1.9 MPa and/or the operating temperature is 95°C), but it is unlikely that any screening criteria will be more optimistic than the IAEA guidance. Furthermore, most regulators require all energised systems (i.e. both low and medium energy systems) to be assessed, albeit, the

Validity: until next update or archiving

Version: 0.1 (Draft)

level of detail may vary depending on the nature of the hazard, design detail and use of bounding hazard scenarios.

Exclusions and screening criteria are used to bound the scope of the HEPF and represent a significant difference between the approaches of the Hazards TESG members. There are clear differences between the regulatory approaches for exclusionary criteria, with the Chinese Regulator allowing for exclusions to be identified and the UK Regulator not applying any exclusion for HEPF.

For example, the acceptability of leak-before-break arguments as an exclusionary criterion varies between Hazards TESG members. Similar debate has been held by other MDEP WGs [e.g. Ref. 6]. There are also differences between regulators on the acceptability of time at risk, utilisation, and geometry arguments for exclusions. Those regulators that do not accept exclusionary arguments as primary safety claims would expect an assessment of the consequences of HEPF for relevant systems from the HPR1000, assuming a full pipe break, unless an alternative justification could be provided for their continued exclusion or they are screened from further consideration based on appropriate screening criteria. It is noted that IAEA SSG-64 [Ref. 5] considers the undertaking of consequence analysis of a full pipe break as good practice to demonstrate the robustness of a design.

With regards to screening, the regulators agree that both deterministic and probabilistic screening criteria are appropriate for use. In applying the screening criteria consideration should be given to the plant configuration, geometry, and location of SSCs important to safety. Potential consequential internal hazards should also be identified for consideration in the analysis. Hazard combinations may be screened out when the probability of occurrence is below a threshold (typically  $10^{-7}$  per annum or lower) but such approaches should be sufficiently justified. However, good practice is moving beyond simple frequency screening. For example, Appendix 1 of SSG-64 (Ref. 5) highlights multiplying numbers together should be treated with caution and reminds the reader that the first hazard may affect the frequency or damage potential of a second hazard. Furthermore, it may still be reasonable to enhance robustness of a design even for a particular combination of hazards with low frequency if the potential consequences warrant such design enhancements.

Validity: until next update or archiving

Version: 0.1 (Draft)

The screening process can be used to identify appropriate bounding scenarios, which can then be applied in the subsequent analysis to ensure that the design is robust against the HEPF hazard (and associated combinations).

One topic discussed by the Hazards TESG, is that the UK Regulator allows for identification of highest integrity components (HIC); items whose failure is considered to be less frequent than 10-7. However, this is not an exclusionary criterion in the normal sense. To satisfy the HIC claim items are subject to robust assessment of detailed evidence, over and above what is considered relevant good practice and including evaluation of the consequences of failure. Only once all necessary evidence has been provided and assessed will a claim of HIC be accepted; and the items can then be screened out of further analysis as a hazard contributor.

Irrespective of the HIC designation the expectations of internal hazards remain, and any hazards that could impact the HIC should be identified and assessed. It is the UK's expectation that a new nuclear power plant (NPP) design should demonstrate that the plant layouts are optimised to eliminate all potential hazards to HICs, so far as is reasonably practicable. Where this is not practicable through the optimisation of the layout, then robust safety measures should be adopted to protect against and/or mitigate any hazard effects. Any hazards that remain, are within the design basis threshold and still provide a challenge to the HIC should be quantified and consequences conservatively assessed to demonstrate that the integrity of the HIC remains and the risks are demonstrated to be ALARP.

All regulators agree that safety trains should be segregated where practicable or protected, to prevent consequential failures resulting from hazards, including pipe failures. Where divisional barriers are included for protection of safety trains then these should be designed to withstand bounding load cases, which should include consideration of combined hazard loadings.

#### **ANALYSIS METHODS**

Following the application of exclusionary and screening criteria, the remaining HEPF hazards screened-in to the assessment should be analysed. The HPR1000 design has been analysed for several HEPF hazards.

Validity: until next update or archiving

Version: 0.1 (Draft)

All regulators agree that it is for the designer / vendor to demonstrate that the specific deterministic safety analysis methods used as part of the design basis analysis are suitable and sufficient. It is expected that both global and local effects should be considered, including combined consequential effects. In doing so the designer / vendor should provide appropriate characterisation of the event sequences to identify all simultaneous loads on the protective barriers, safety measures and SSCs. For SSC substantiation (the generation of evidence that demonstrates a claim on SSCs can be achieved, such as by calculation, modelling or research) the design basis analysis should consider consequential hazards resulting from pipe interactions. The response of both SSCs and barriers to combined loads (e.g. pipe whip, jet impact, steam release and flooding etc.) should be evaluated. The analysis should be suitably conservative, use appropriate codes and tools, supported by robust justification of their relevance, and appropriately verified and validated for the application applied.

With respect to the detailed analysis, there exist some similarities and differences between regulatory approaches and how conservatism is included in the design basis analyses. It is generally accepted that the initiating hazard and associated faults should be assumed to occur in the most onerous, normally permitted operating conditions and where appropriate, the bounding unmitigated fault scenarios identified via the screening process should be applied. However, arguments relating to leak-before-break are not accepted as primary safety claims by some members of the Hazards TESG.

Deterministic safety analysis for design extension conditions without significant fuel degradation should also be provided to demonstrate the absence of cliff edge effects and identify the margins available before loss of safety functions. The Chinese Regulator has satisfied themselves that the HPR1000 design considers cliff edge effects. The UK Regulator would expect for hazards with a frequency below the design basis threshold, analysis to be undertaken on a best estimate basis. The UK Regulator would also expect sensitivity analysis to be provided for systems with operating limits and conditions near the initial screening criteria to demonstrate the absence of cliff edge effects on other SSCs.

#### SUMMARY OF DESIGN AND POTENTIAL IMPACT

The analysis provided for HEPF in the HPR1000 design conservatively assumes any SSCs present in the room where the hazard occurs are lost, and a range of hazard combinations are considered. Other protective, defense-in-depth measures include

Validity: until next update or archiving

Version: 0.1 (Draft)

barriers, anti-whip devices and restraints. However, due to the differences in regulatory approaches it is recognised that additional analysis may be required to satisfy the specific expectations of the different regulators.

#### IV. DROPPED LOADS

This section compares the regulatory approaches of the HPR1000 Hazards TESG with respect to dropped loads to identify areas of common practice and key differences. The implications of these differences in regulatory approach are considered with respect to the design of the HPR1000.

#### **SCOPE: EXCLUSIONS AND SCREENING CRITERIA**

Unlike the HEPF hazard, there is less agreement on the scope of the dropped loads hazard between members of the Hazards TESG. It is generally accepted that consequences of dropped loads for lifting equipment should be considered, as well as other falling objects that may occur consequentially as a result of structural failures caused by external and/or internal hazards, or human error (such as incorrect operation, slinging or attachment of a load to lifting equipment). Dropped loads can impact SSCs providing safety functions and should therefore be considered as a potential initiator of fault sequences with nuclear safety consequences. HAD102/04 provides the requirements considered for the HPR1000 design and there has been some consideration of dropped loads in the design.

All regulators expect potential dropped load hazards to be suitably identified and characterised. However, there is clear difference between the regulatory approaches for exclusionary criteria of dropped loads and screening criteria. The Chinese Regulator requires vendors / designers to postulate dropped loads for every lifting or handling device. However, it is generally expected that the vendors / designers will be able to demonstrate that the reliability of the lifting equipment is such that the hazard can be effectively discounted. This is because the Chinese Regulator permits the use of single failure proof cranes arguments to exclude cranes, and associated drop load hazards from further analysis. Defense-in-depth is expected to be provided including via the configuration of handling equipment avoiding SSCs and the integrity of items being lifted, such as fuel casks.

Validity: until next update or archiving

Version: 0.1 (Draft)

In comparison the UK Regulator expects consideration of the consequences from dropped loads for all lifting operations that occur in the vicinity of nuclear safety significant SSCs that would be susceptible to failure in the event of a dropped load occurring. This includes, for example swing loads and crane collapse. For that lifting equipment not analysed for dropped loads in the HPR1000 design, the UK Regulator would expect them to be considered in the GDA, and if necessary additional analysis to be undertaken to demonstrate that the risks from dropped load are reduced to be as low as reasonably practicable.

Those cranes and objects that could potentially fall and are not excluded from the assessment, depending on the regulatory jurisdiction and approach, should then enter the screening process. Regulators agree that both deterministic and probabilistic screening criteria are appropriate for application. For example, dropped loads can be screened from the analysis if the consequences can be shown to be negligible, or if the frequency of occurrence is below a threshold (typically an event frequency or a fault sequence frequency below once in ten million years (10-7)). The screening process is expected to retain all faults associated with both types of hazard (dropped loads and falling objects) that have the potential to make a significant contribution to the overall risks from the facility and then analyse the potential consequence of these faults.

#### **ANALYSIS METHODS**

Following the application of exclusionary and screening criteria, the analysis of the remaining dropped loads and falling objects should be analysed. The HPR1000 has analysed a number of dropped loads, associated with cranes, and falling objects. It is also noteworthy that the Chinese Regulator has specifically undertaken additional analysis of dropped loads in the fuel building [Ref. 7] to show that the risks are tolerable.

It is generally agreed that deterministic analysis should be used for those screened-in dropped loads. There are varying expectations as to how this analysis should be undertaken and how conservatism is included. In general, the Chinese Regulator would typically expect that vendors / designers demonstrate that lifting equipment is sufficiently reliable to claim single failure proof criterion, and therefore the safety case will focus on defense-in-depth claims. In comparison the UK Regulator will expect analysis of the worst-case, unmitigated, fault condition, (i.e. a drop from the maximum height) with effects considered for all SSCs that could potentially be impacted. This includes potential effects

Validity: until next update or archiving

Version: 0.1 (Draft)

of dropped loads on barriers such as penetration, spalling, cone cracking and perforation.

All regulators expect defense-in-depth to be demonstrated against dropped loads. This can include, but not be limited to:

- A consideration of whether the lift can be practicably eliminated.
- Movement plans that avoid, where reasonably practicable to do so, the lifting over/near safety significant SSCs, and the height of the lift minimised.
- Measures taken to prevent the lifting of excessive loads.
- Items / packages containing nuclear matter / radioactive materials are designed to retain their integrity following an impact resulting from a dropped load.
- Lifting equipment can only be used in permitted states.

All regulators in the Hazards TESG agree that the analysis of dropped loads should result in the determination of the limits and conditions of operation of, for example, the lifting equipment, detailed load paths, and systems and administrative controls that need to be in place to control the lifts. Such limits and conditions would need to be followed by the plant operator.

#### SUMMARY OF DESIGN AND POTENTIAL IMPACT

The HPR1000 considers dropped loads and falling objects and has considered these hazards in the defense-in-depth of the plant. However, it is recognised that the due to the different regulatory expectations in relation to exclusionary criteria that additional analysis may be required to satisfy the expectations of the different regulators.

#### V. COMBINED HAZARDS

This section compares the regulatory approaches of the HPR1000 Hazards TESG with respect to hazard combinations to identify areas of common practice and key differences. The implications of these differences in regulatory approach are considered with respect to the design of the HPR1000.

#### SCOPE: EXCLUSIONS AND SCREENING CRITERIA

The identification, screening and analysis of combined hazards is a multidisciplinary subject that requires a detailed understanding of the layout and hazards within the NPP

Validity: until next update or archiving

Version: 0.1 (Draft)

design. One of the key sources of multi-hazards is the failure of high energy pipes (see HEPF section above) that can result in a number of consequential hazards including: pipe whip, jet loads, steam release, blast effects and internal flooding. Therefore, the NPP design needs to demonstrate capacity to withstand the combined effects from the combined hazard loads particularly for those areas of highest risk, such as areas where HIC exist.

All regulators involved with the HPR1000 MDEP WG recognise the importance of assessing the combination of events that could impact SSCs important to safety. For the HPR1000 design this is captured in the Chinese guidance HAF-102-2016 and sets out the expectation that where analysis identifies combination of events that can lead to operational, or accident condition the event shall be considered in the design basis of the plant. This guide prescribes specific regulatory expectations on the methodology of combined hazards and there are also related requirements in the Safety Guide HAD102/17-2006 "Evaluation and verification of the Safety of Nuclear Power Plants".

The UK Regulator has specific guidance on the expectations for assessment of combination hazards, where it defines the following classifications, which are consistent with those adopted in Ref. 5:

- Unrelated (independent) hazards: when more than one internal and/or external
  hazard applies simultaneously. This can be the case, for example, of nominally
  frequent events such as internal fire and flooding when there is no causation link
  between them.
- Consequential Hazards: an internal or external hazard directly poses one or more additional hazards to plant and structures (e.g. seismic hazard leads to an internal fire that activates a water-based fire suppression system leading to water spray and flooding effects).
- Correlated Hazards: A common cause results in multiple hazard(s) that occur simultaneously. An example of this would be pressure part failure giving rise to pipe whip impact and flooding.

All regulators recognise the importance of adequate screening highlighting the reliance of deterministic and probabilistic methods. The UK Regulator provides specific guidance

Validity: until next update or archiving

Version: 0.1 (Draft)

on screening techniques to demonstrate the NPP design considers relevant hazard combinations.

All regulators agree on the adoption of redundancy and segregation to ensure that hazards cannot lead to the loss of multiple safety trains. To achieve this, all regulators strive to ensure that the plant design meets the guidance in IAEA SSG-64 (Ref. 5) and national design practices ensuring that hazards are considered in the design, and optimisation of plant layout minimises the effects of hazards.

For the optimisation of layout and hazard protection all regulators recognise the importance of civil barriers (including protecting penetrations through those barriers) for the provision of passive means to provide protection against the maximum credible loads. There is a general regulatory requirement / expectation that barriers required for nuclear safety should be demonstrated to maintain their integrity under all hazard conditions (including combinations) and deliver their safety functions. This sets out the need for barriers to be substantiated to withstand multiple hazards.

#### **ANALYSIS METHODS**

All regulators expect hazard analysis and the identification of combined hazards via a combination of deterministic and probabilistic approaches. The assessment of combined loads is universally agreed to be essential in demonstrating the safety of a NPP design. Bounding load cases are considered suitable for use in the analysis, including those resulting from hazard combinations, so long as they are suitably justified.

For example, the UK Regulator recommends considering the worst-case unmitigated hazard conditions, (e.g. most onerous loads including combinations of loads), as a starting point for the assessment. Doing so (e.g. by assuming safety measures are absent or fail to operate) can reveal the most onerous event consequences and hence ensure that the nuclear safety significance of measures and assumptions on which the design depends are appropriately recognised. Where gaps / weaknesses are identified in the design additional measures (engineering or procedural) may be required to reduce the hazard loads or effects. ONR SAPs paragraph 155 provides a hierarchy of safety measures, with a preference for those towards the top of the hierarchy (e.g. passive safety measures compared with mitigative measures). It should be noted that this hierarchy does not prevent other measures being implemented as part of the plant's defense-in-depth. It is the UK Regulator's expectation that the safety case clearly

Validity: until next update or archiving

Version: 0.1 (Draft)

presents the full range of options considered as part of optioneering process to demonstrate that the measures adopted reduce the risks to be as low as reasonably practicable. This stepwise approach provides a basis to understand the hazards and associated risks to nuclear safety for the NPP design and to enable proportionate assessment of the safety case claims, arguments and evidence (as provided by duty holders to demonstrate that the risks from hazards have been reduced to ALARP).

Analysis of the plant against the derived load cases should be undertaken to enable assessment of the tolerability of the NPP design. Consideration of loads resulting from hazard combinations is important in ensuring that the design of passive, multi-hazard barriers is adequate. It is expected that these barriers should be substantiated to be tolerant of bounding hazard loads including combination of hazards. Furthermore, the analysis should underpin the identification and the importance of functional requirements of safety measures that address the hazard.

The regulators expect that the design layout should in the first instance be optimised to eliminate hazards. Where this is not reasonably practicable the design should demonstrate an iterative approach for reducing hazard risks applying a hierarchy of safety measures and defense-in-depth. This approach should adequately demonstrate that hazard effects have been considered and priority given to ensuring segregation of key safety systems through the provision of passive barriers. The analysis should ultimately demonstrate that the layout is optimised such that the risks to SSCs from hazards and hazard combinations are as low as is reasonably practicable. Any areas of exception (i.e. where multiple safety trains pass through a single room) need to be identified and suitably justified to show that there is no significant increase in risk.

#### SUMMARY OF DESIGN AND POTENTIAL IMPACT

The HPR1000 design considers hazard combinations based on the relevant HAF and HAD codes. The design includes the provision of passive barriers to protect SSCs against the effects of hazards and hazard combinations. This includes segregation of the various safety trains where reasonably practicable to do so. However, due to the differences in regulatory approaches it is recognised that additional analysis may be required to satisfy the specific expectations of the different regulators.

Version: 0.1 (Draft)

#### VI. CONCLUSIONS

This technical report presents a summary of the regulatory approaches relevant to hazards of the members of the HPR1000 Hazards TESG. It is based on the detailed information provided by members of the Hazards TESG in response to the questionnaire provided in the appendix. The responses to the questionnaire have been compared to identify areas of common regulatory approach and differences.

Overall, all member countries ensure that their national guidance documents are aligned with IAEA guidance relevant to hazards. Therefore, at a principal level, the regulatory expectations for hazards are similar between the members of the Hazards TESG. However, there are some notable differences in the application of these high-level principles with respect to identification, screening, and characterisation of hazards and in the detailed application of regulatory approaches for assessment purposes.

The differences between regulatory approaches have been explored for a number of pertinent, typical hazards and the potential impact of these differences for the design of the HPR1000 reactor discussed. Given the varying status of each member's regulatory assessment of the HPR1000 reactor design it has not been possible to identify any specific design changes that may result from different regulatory expectations relevant to hazards. However, it is possible to identify where additional analysis may be required to ensure the design meets national expectations. For example, the UK Regulator does not accept leak-before-break arguments as a principal means of demonstrating adequate safety. Consequently, additional analysis is needed to demonstrate that the consequences of a HEPF have been adequately accounted for and that the risks for the design are as low as reasonably practicable.

With respect to common practice, all members agree that:

- I. IAEA guidance is considered good practice and each member's guidance is aligned with IAEA documentation relevant to hazards.
- II. Identification, characterisation, and screening of hazards (including combinations) is good practice.
- III. Individual hazards and combinations of hazards are considered in the design of the HPR1000 design, albeit individual national regulators may expect some additional hazards / combinations to be considered.
- IV. Application of bounding hazard scenarios is an appropriate approach.

Validity: until next update or archiving

Version: 0.1 (Draft)

V. Application of suitable screening criteria to bound the hazards analysis is considered appropriate.

VI. Various approaches should be used to analyse hazards at different annual probability of exceedance including: deterministic approaches, design basis analysis, beyond design basis analysis (including demonstrating an absence of cliff edge effects), probabilistic safety analysis and severe accident analysis.

## APPENDIX FOR SPECIFIC GUIDANCE

## **Hazards TESG Technical Report**

The following questionnaire was developed by members of the hazards TESG following the 3<sup>rd</sup> meeting of the HPR1000 WG and the responses were discussed during the 4<sup>th</sup> HPR1000 WG meeting held at Fangchenggang, China in September 2019.

The Hazards TR is based on the detailed information contained in the table below.

Hazard	NNSA Response	ONR Response	NNR Response	ARN Response

Hazard	NNSA Response	ONR Response	NNR Response	ARN Response
	<b>No. NS-G-1.11</b> Protection against Internal Hazards other than Fires and Explosions in the Design of Nuclear Power Plants	ONR expects the assessment of the consequences of dropped loads, from all lifting operations on susceptible nuclear safety significant SSCs. In general the scope of assessment should consider:	The following text from Section 5 of NNR Draft Specific Nuclear Safety Regulations: Nuclear Facilities mentions falling objects:  "(2) Internal and external hazards	ARN's expectations are aligned with IAEA safety standards. With respect to hazards analysis, it is expected that the applicant assess the
	2.18. In this systematic analysis, among the important secondary effects the following should be evaluated:  Falling objects. There may be circumstances in which a pipe whip or a missile can damage the supporting structure of a heavy object located above a safety system such that an object falls, possibly causing further damage. It may in certain cases be possible to show that the falling object cannot cause unacceptable damage. If not, either the supporting structure should be modified	<ul> <li>Whether as a result of lifting operations specifically, or intended or unintended drop of plant from height have been identified and considered.</li> <li>The analysis of dropped loads results in the determination of the limits and conditions of operation of, for example, the lifting equipment, detailed load paths, and systems and administrative controls that need to be in place.</li> <li>Claims on "high integrity cranes" without the requisite consequences analysis of the dropped loads are not accepted.</li> </ul>	(c) The design of a facility shall take due account of internal hazards such as fire, explosion, flooding, missile generation, collapse of structures and falling objects, pipe whip, jet impact and release of fluid from failed systems or from other facilities on the site. Appropriate features for prevention and mitigation shall be provided to ensure that safety is not compromised."  For further guidance, the NNR considers that the recommendations of the following IAEA publications,	consequences of the dropped loads on items important to safety.  For ARN is acceptable that drops are more likely to occur from the handling of plant equipment or from fuel handling lifts. Also, if heavy items of plant equipment are located at significant heights, an evaluation should be made of the possible hazards associated with dropping such equipment. In all cases, exclusion from assessment has to be justified based on the fact that the probability of such event is negligible.
	to withstand the missile impact or means should be provided to prevent such an impact.  HAD102-04 3.2.2 Dropping of heavy equipment.	<ul> <li>The maximum fault condition height e.g. double blocking height and mass should be assumed.</li> <li>The various potential effects of dropped loads on</li> </ul>	address the hazard of dropping heavy equipment as a result of internally initiated events:	What are the regulatory expectations for:
	If heavy items of plant equipment are located at significant heights, an evaluation should be made of the	barriers should include penetration, spalling, cone cracking and perforation.  Are there any exclusions and what is the reason?	IAEA SSG-64 "Protection against Internal Hazards in the Design of Nuclear Power Plants, The section on heavy load drop starting at para. 4.173 of IAEA SSG-62, "Design of Auxiliary Systems and Supporting	The methodologies used in the deterministic analysis by vendors?
	possible hazards associated with dropping such equipment, if the probability of this event is not negligible.	There are no exclusions from assessment.	Systems for Nuclear Power Plants", IAEA SSG-63, "Design of Fuel Handling and Storage Systems for Nuclear Power Plants".	ARN does not specify a detailed analysis methodology. However, based on NUREG 0612 expects that the analyses of postulated load drops
	Scope of Analysis  Dropped loads assumed to occur as a result of a lifting device failure if the lifting devices can no longer control the loads;	What are the regulatory expectations for:  The methodologies used in the deterministic analysis by vendors?	Furthermore, IAEA SSG-67, "Seismic Design for Nuclear Installations", and IAEA SSG-74, "Maintenance, Testing, Surveillance and Inspection in Nuclear Power Plants", provide recommendations on seismic design and qualification, and on maintenance, surveillance and	should as a minimum include the following considerations:  • The load is dropped in an orientation that causes the most severe consequences.  • The load may be dropped at any location
	Dropped loads are postulated from every lifting or handling device except the ones which are satisfied with 'single failure proof'.	<ul> <li>The worst-case unmitigated maximum fault condition height e.g. double blocking height and mass should be assumed.</li> <li>Effects to all interacting SSCs should be assessed e.g.:         <ul> <li>The various potential effects of dropped loads on</li> </ul> </li> </ul>	in-service inspection, respectively, that together will lead to high integrity lifting systems in operation.  Are there any exclusions and what is the reason?	<ul> <li>in the crane travel area where movement is not restricted by mechanical stops or electrical interlock.</li> <li>The analysis should postulate the "maximum damage" that could result, i.e.,</li> </ul>
	Exclusions during Dropped Loads safety evaluation  The reliability of the lifting equipment should be such that dropping of the load can be effectively discounted, for example, by the use of single failure proof cranes.	<ul> <li>barriers should include penetration, spalling, cone cracking and perforation.</li> <li>Demonstration Items / packages containing nuclear matter are designed to retain their integrity following the worst-case impact.</li> <li>Demonstration that Optioneering has been undertaken to identify whether the lifting activity is actually necessary, and to identify the preferred</li> </ul>	The following text from Section 5 of NNR Draft Specific Nuclear Safety Regulations: Nuclear Facilities implies that in principle all categories of dropped loads should be considered in the assessment:  "(2) Internal and external avanta shall be identified based.	<ul> <li>the analysis should consider that all energy is absorbed by the structure and/or equipment that is impacted.</li> <li>Credit may not be taken for equipment to operate that may mitigate the effects of the load drop if the equipment is not required to be operable by the technical specifications when the load could be</li> </ul>
	Dropped loads of spent fuel <b>cask are mainly considered</b> in the design (PSAR 3.5.1.1.3).  The <b>design of spent fuel cask crane</b> takes into account	method and equipment for undertaking the lift.  • Assessment to determine if lifting over/near safety significant SSC's can be avoided, and the height of the lift minimised so far as is reasonably practicable.	<ul> <li>(a) Internal and external events shall be identified based on a comprehensive hazard analysis.</li> <li>(b) All foreseeable internal hazards and external hazards, including the potential for human induced events directly or indirectly to affect the safety shall be</li> </ul>	dropped.  The process for identification, screening and quantification of credible bounding events
	single failure and redundancy design, and is equipped with necessary safety devices, which has high safety reliability. The lifting mechanism of spent fuel cask crane adopts a double wire rope winding system and multiple brakes as redundancy protection measures. 		parameter will not lead to a disproportionate increase in radiological consequences, ie there should be no cliff edge effect. The severity and frequency of the initiating event should be amongst the parameters considered. The aim is to be conservative without being overly pessimistic.  The use of probabilistic analysis?  ONR expects that the analysis should apply an appropriate combination of engineering, deterministic and probabilistic methods in order to:  Understand the behaviour of the facility in response to the hazard; and Confirm high confidence in the adequacy of the design basis definition and the associated fault tolerance of the facility.		
Internal	Missiles analysis (such as from valves and turbine	Missiles analysis (such as from valves and turbine	Missiles analysis (such as from valves and turbine	Missiles analysis (such as from valves and turbine
missiles	disintegration) How is the scope of hazards analysis defined?	disintegration) How is the scope of hazards analysis defined?	disintegration) How is the scope of hazards analysis defined?	disintegration) How is the scope of hazards analysis defined?
	(HAD102/04, SRP3.5.1.1)  a. Missiles from component over speed failures; b. Missiles generating from high energy fluid system failures; c. Missiles caused by or as a consequence of gravitational effects. (managed in dropped load)  Are there any exclusions and what is the reason?  a. The probability of generating missiles is small enough to be accepted without considering the consequences. b. Although the probability of generating missiles is slightly higher, the comprehensive consequences can be accepted from the view of safety.  Through using the appropriate design standards, specification of materials and equipment, carrying out strict quality assurance requirements, quality control inspection during manufacture, operation and maintenance, equipment and components apply nuclear related standards (e.g., RCC-M 1,2,3,or ASME 1,2,3), probability of occurrence of internal missiles can be exclude from the creditable missile source list.  What are the regulatory expectations for: The methodologies used in the deterministic analysis by vendors?	<ul> <li>identified: from pressurised vessels, pipework and components, rotating machinery and systems which contain explosive mixtures.</li> <li>All assumptions should be made explicit. The consequences depend on key assumptions made in the evaluation of the missile energy such as size and geometry of the fragments ejected, the trajectory of the missiles and any credited loss of energy through interaction with equipment or structures (e.g. rotating machinery casing, walls).</li> <li>Trajectory of missiles is subject to high levels of uncertainty as a result of the uncertainty inherent to the missile fragment formation, therefore appropriate sensitivity analysis should be undertaken to demonstrate there are no cliff edge effects.</li> <li>Bounding arguments should be presented e.g. consider that damage from internal missiles may occur in any direction from the source / loss of SSCs in the same location.</li> <li>Probabilistic arguments alone are not accepted to exclude assessment of missile sources or impacts/ strike on SSCs or nuclear safety significant plant.</li> <li>ONR expectations for Turbine disintegration:</li> </ul>	The following text from Section 5 of NNR Draft Specific Nuclear Safety Regulations: Nuclear Facilities mentions missile generation:  "(2) Internal and external hazards  (c) The design of a facility shall take due account of internal hazards such as fire, explosion, flooding, missile generation, collapse of structures and falling objects, pipe whip, jet impact and release of fluid from failed systems or from other facilities on the site. Appropriate features for prevention and mitigation shall be provided to ensure that safety is not compromised."  For further guidance, the NNR considers that the recommendations of the following IAEA publication address the hazard of internal missiles as a result of internally initiated events: The section on internal missiles starting at para. 4.78 of IAEA SSG-64 "Protection against Internal Hazards in the Design of Nuclear Power Plants".  Are there any exclusions and what is the reason?  See comments in Drop load section above.  What are the regulatory expectations for:	<ul> <li>ARN's expectations are aligned with IAEA:</li> <li>Sources of possible missiles should be identified, included but not limited to:  - Valves in fluid systems that operate at high internal energy should be evaluated as potential sources of missiles  - Failure of high speed rotating equipment include:  (a) Fan blades; (b) Turbine disc fragments or blades; (c) Pump impellers; (d) Flanges; (e) Coupling bolts.  - Failure of pressure vessels</li> <li>The frequency, the possible magnitude of kinetic energy and the likely size and trajectory of missiles should be estimated. 	Relevant safety classified structures and components should be designed to withstand all relevant loading resulting from operational states and design basis accidents including those resulting from internal and external hazards. (NS-G-1.2)	Civil barriers are a key claim in internal hazards safety cases. ONR expectations required that the Civil barrier is adequately designed to protect against a number of credible internal hazards individually and in combination (combined hazards).  Substantiation of barriers provides the requisite evidence	For each identified hazard combination sequence, the analysis should consider any deterioration or damage to SSCs important to safety (including hazard barriers) after being subjected to each of the various hazards. For example, for a pipe failure that leads to a missile and a subsequent flood, the analysis of the capability of a hazard barrier to withstand the hydrostatic loads from flooding will need to take account of any damage	
	The design details are as follows:  HPR1000  For HPR1000, as some general design principles, the design of safety classified structures and components considered the internal and external effects. For example, the containment of Reactor Building and safety classified	<ul> <li>All barriers should be identified and listed in the hazard schedule.</li> <li>All loads should be characterised.</li> <li>All design codes and analytical methods should be made explicit.</li> <li>All acceptance criteria and margins of safety should be stated.</li> </ul>	caused by successive or simultaneous hazards (e.g. the failure of pressurised parts, which could lead to pipe whip, jets, and steam pressure effects on barriers or other SSCs important to safety). Hazard	NNSA Response	ONR Response	important SSCs against pipe break impact, anti-whip devices are employed.  More generally, based on p.57 of IAEA -TECDOC-1791:  Physical separation of redundant trains and components is efficient against CCFs and other dependent failures originated by harsh environmental conditions and the effects of several hazards, as well as the direct impact of mechanical or electrical failures of one train on the redundant train.  Earthquakes, fires and floods among other hazards have the potential to fail or degrade the condition of many plant SSCs at once. Moreover some of these hazards can induce other hazards as it happened in the Fukushima accident. Physical separation, adequate plant layout and design robustness are at the core of the defensive measures to reduce the impact of hazards, in addition to adequate safety margins and protective measures as well as good operational practices.  Of particular importance is the adequate separation of cable routings of different electrical and instrumentation divisions. A full physical separation of trains might not be feasible in all plant areas. Physical separation can be accomplished either by full separations of trains through qualified barriers, the installation of protections on one train's relevant equipment and the separation by	The expected measures include physical separation that can be accomplished either by full separations of trains through qualified barriers, the installation of protections on one train's relevant equipment and the separation by sufficient distance. The first option gives in general the highest protection. When full separation is not feasible, justification and assessment of a "robust" alternative solution must be done.
			highest protection.	
Fire modelling (including validation & verification)	What are the regulatory expectations for analytical modelling code validation?  Empirical curve method is widely used in fire hazard analysis of nuclear power plants in China. Some applicants are exploring the application of numerical simulation method. If the fire analysis software is used in the project, the applicability of the software in engineering should be evaluated.	What are the regulatory expectations for analytical modelling code validation?  It is ONRs expectation that a modern standards safety case should demonstrate that analysis undertaken in the design base assessment of nuclear safety is relevant, conservative, complete and tolerant to uncertainty. Hazard analysis should be conducted on a deterministic basis, ensuring that all credible hazards (including combination of hazards) are identified, their severity determined and affects to nuclear safety related structures, systems and components assessed.  For all safety case hazard analysis, the safety case should present a clear auditable trial of documentation to underpin the conclusions drawn from the modelling analysis. This should include (but not limited to):	What are the regulatory expectations for analytical modelling code validation?  According to Section 8.7 of NNR RG-0019 "Interim Guidance on Safety Assessments of Nuclear Facilities", the applicant should demonstrate that there is reasonable assurance that the applicant designed a facility that provides for "adequate protection against fires and explosions" and is based on defense-in-depth practices. This should also establish that the radiological consequence from fires is considered in determining how the facility will meet the fundamental safety requirements.  Amongst others, Section 8.7 lists fire protection features and systems that should be used. As such, they [as well as elements from the latest guidance from IAEA SSG-64 "Protection against Internal Hazards in the Design of	What are the regulatory expectations for analytical modelling code validation?  The fire hazard analysis should be developed on a deterministic basis, with the following assumptions:  (a) A fire is postulated wherever fixed or transient combustible material could be present;  (b) Only one fire is postulated to occur at any one time; consequential fire spread should be considered as part of this single event, if necessary;  (c) The fire is postulated whatever the normal operating status of the plant, whether at power or during shutdown.  The fire hazard analysis should take into account any credible combinations of fire and other events. Fire hazard analysis should be complemented by fire probabilistic safety analysis (Fire PSA). PSA is

Hazard	NNSA Response	ONR Response	NNR Response	ARN Response
Huzulu	MANA VESPONSE	accurately identify critical failure modes and their	ואואי עבאליטואב	Auta reshouse
		nature (e.g. ductile or non-ductile) as this is helpful to		
		aid the identification of the actual threshold of failure		
		establish that the hazard varies gradually around the		
		design basis frequency, and that the plant response		
		does not suddenly change in this region, say due to		
		the failure mechanism    demonstrate margin between the design basis and		
		the loss of the design basis safety function that reflects		
		the known uncertainties in both hazard analysis and		
		plant response analysis		
		<ul> <li>demonstrate that loss of safety function should not,</li> </ul>		
		where practicable, lead to another fault condition, ie		
		equipment should be designed, where practicable,		
		to fail safe following an external hazard		
		Note: the design basis hazard value may well be very		
		much greater than the site-specific hazard analysis value,		
		implying a large in-built margin to the design basis hazard		
		definition.		
		Beyond design basis Analysis		
		EHA.18 introduces the need to analyse fault sequences		
		initiated by internal and external hazards beyond the		
		design basis should through an appropriate combination		
		of engineering, deterministic and probabilistic		
		assessments to understand the hazard level at which		
		safety functions could be lost.		
		The use of good engineering practice applied to protect		
		and mitigate conservatively defined non-discrete faults		
		initiated down to the 10-4/yr. exceedance frequency		
		value, is likely to provide a level of risk control that will		
		satisfy the SAP risk targets. However, because non-discrete		
		EHs are described by hazard curves covering a wide		
		range of frequencies, parts of which extend well below		
		10-4/yr. the BDB component may contribute significantly		
		to facility risk. For non-discrete hazards therefore, BDBA is		
		important and can help to define the hazard severity at		
		which plant / SSC failure or loss of safety function occurs.		
		Where a design basis is established for a discrete EH and a		
		hazard curve is not defined, the possibility of an event		
		more severe than the design basis may also need		
		consideration. This applies if the event initiation frequency		
		is difficult to determine or if the IEF is less than the design		
		basis criterion. A possible approach to demonstrate		
		sufficient margin to loss of safety function for the former is		
		to select one or more hazard-specific loading values that		
		are higher than the design basis event loads and		
		demonstrate that the safety functions are not		
		endangered by these loads. The severity of the loading

Hazard	NNSA Response	ONR Response	NNR Response	ARN Response
	·	values may be chosen to correspond to a safety margin	·	·
		that is considered adequate. The use of a MCE for such		
		analyses may also be useful, but caution should be		
		exercised if the selected MCE is very severe, since this		
		might lead to the conclusion that for such an event		
		reasonably practicable plant improvements do not exist.		
		Selecting a more reasonable choice of BDB event may		
		provide opportunities for reasonably practicable plant		
		improvements.		
		For the latter, where the hazard occurrence frequency is		
		estimated to be below the design basis criterion but		
		above the EH screening criterion the fault analysis		
		guidance given in SAPs paragraph 609-610 is applicable.		
		In this case it is expected that assessment of the likely		
		accident progression and potential consequences should		
		take place to allow consideration of reasonably		
		practicable means of protection or mitigation of the		
		consequences such that the risks are ALARP.		
		It has previously been accepted that one satisfactory		
		approach to the demonstration of absence of a		
		disproportionate increase in consequences is via an EHs PSA. This has the merit of exploring the response of the		
		plant to a wide range of hazard levels and is accepted		
		internationally as a reasonable approach for EHs.		
		internationally as a reasonable approach for this.

		capacity of the tanks. The MCE concept is useful for	NNR recognises that nuclear facilities are quite broad	
		quickly estimating worst-case scenarios and is generally	and such a definition is more reasonable if it is applied to	
		applied to hazards whose nuclear safety implications are	power reactor facilities as they demand a higher level of	
		minor. Quite often, the Licensee is able to demonstrate in	safety. Therefore, the NNR follows a graded approach	
		a straightforward way that, even at the MCE level, the	when applying these criteria.	
		nuclear safety implications are negligible and therefore		
		the hazard can be screened out from further		
		consideration. The MCE can also be useful in helping to		
		define a design basis event when probabilistic methods		
		for the hazard in question carry large uncertainties, and		
		also provides a useful insight for BDBA		
		Some hazards may not be amenable to the derivation of a design basis event based on frequency. In principle, it may also be possible to develop a MCE for a non-discrete hazard. In such cases a surrogate Maximum Credible Event, supported by scientific evidence, may be defined.		
		For example, if the hazard curve is asymptotic to some		
		upper value of severity, or if a relevant physical limit can		
		be defined that limits hazard severity.		
		Where hazards are not amenable to the derivation of a		
		design basis event based on frequency, a surrogate MCE,		
		supported by scientific evidence, may be defined. The		
		severity of the surrogate MCE should be chosen and		
		justified to reach an equivalent level of safety (that is, it		
		should be compatible with the principles of SAP FA.5).
